Upgrade Path for Fused-Silica Interferometers

LIGO O4 configuration:

- ~**350 kW** laser power in the arm cavities
- ~ **5 dB** frequency-dependent squeezing

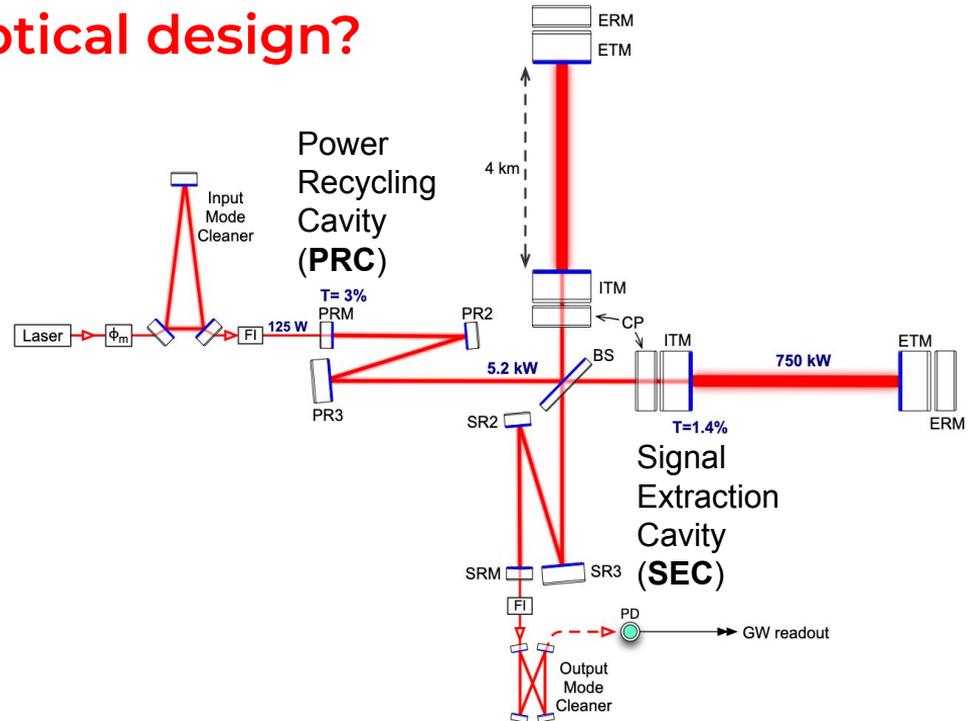

Quantity	A+ (O5)	A# (O6)
Arm length (km)	4	4
Wavelength (nm)	1064	1064
Mirror mass (kg)	40 →	100
Mirror diameter (cm)	34 →	46
Arm power (MW)	0.8	1.5
Squeezing (dB)	6	10

Upgrade Path for Fused-Silica Interferometers

Why not just scale up LIGO optical design?

Quantity	A+ (O5)	A# (O6)	CE
Arm length (km)	4	4	40
Wavelength (nm)	1064	1064	1064
Mirror mass (kg)	40	100	320
Mirror diameter (cm)	34	46	70
Arm power (MW)	0.8	1.5	1.5
Squeezing (dB)	6	10	10

Cosmic Explorer: Why Not Just Scale up LIGO Design?

1) Unique challenges arise from a 10x longer arm length ([CE-G2300033](#))

- Minimum beam size for 40 km arms is ~12 cm. For < 1 ppm clipping loss on ITMs, require **~70 cm ITMs**. Beamsplitter should be **$\sqrt{2}$ bigger*** (at 45° AOI). *1 m diameter unfeasible?*
 - ➔ Consider alternate layouts with a **different beamsplitter location**
- SEC resonance **approaches detection band** with 40 km or 20 km arms ($f_s \propto 1/\sqrt{L_s}$)
 - ➔ SEC length must be kept to **< 200 m** (40 km arms) or **< 90 m** (20 km arms)
- FSR of 40 km arms is 3.75 kHz. With same arm finesse, **DARM pole is 10x lower** ($f_p \propto 1/L_a$)
 - ➔ Need **10x higher SEC finesse** to recover same bandwidth

Cosmic Explorer: Why Not Just Scale up LIGO Design?

1) Unique challenges arise from a 10x longer arm length ([CE-G2300033](#))

- Minimum beam size for 40 km arms is ~12 cm. For < 1 ppm clipping loss on ITMs, require ~70 cm ITMs. Beamsplitter should be $\sqrt{2}$ bigger* (at 45° AOI). *1 m diameter unfeasible?*
 - ➔ Consider alternate layouts with a **different beamsplitter location**
- SEC resonance **approaches detection band** with 40 km or 20 km arms ($f_s \propto 1/\sqrt{L_s}$)
 - ➔ SEC length must be kept to < **200 m** (40 km arms) or < **90 m** (20 km arms)
- FSR of 40 km arms is 3.75 kHz. With same arm finesse, **DARM pole is 10x lower** ($f_p \propto 1/L_a$)
 - ➔ Need **10x higher SEC finesse** to recover same bandwidth
- **With a 10x lower arm cavity FSR, nearly all higher-order mode (HOM) resonances will lie in the observation band**
 - ➔ **Precision mode-matching** is critical to suppress noise couplings, squeezing loss, and squeezing angle mis-rotation around the frequencies of these resonances

Impact of SEC Mode-Mismatch

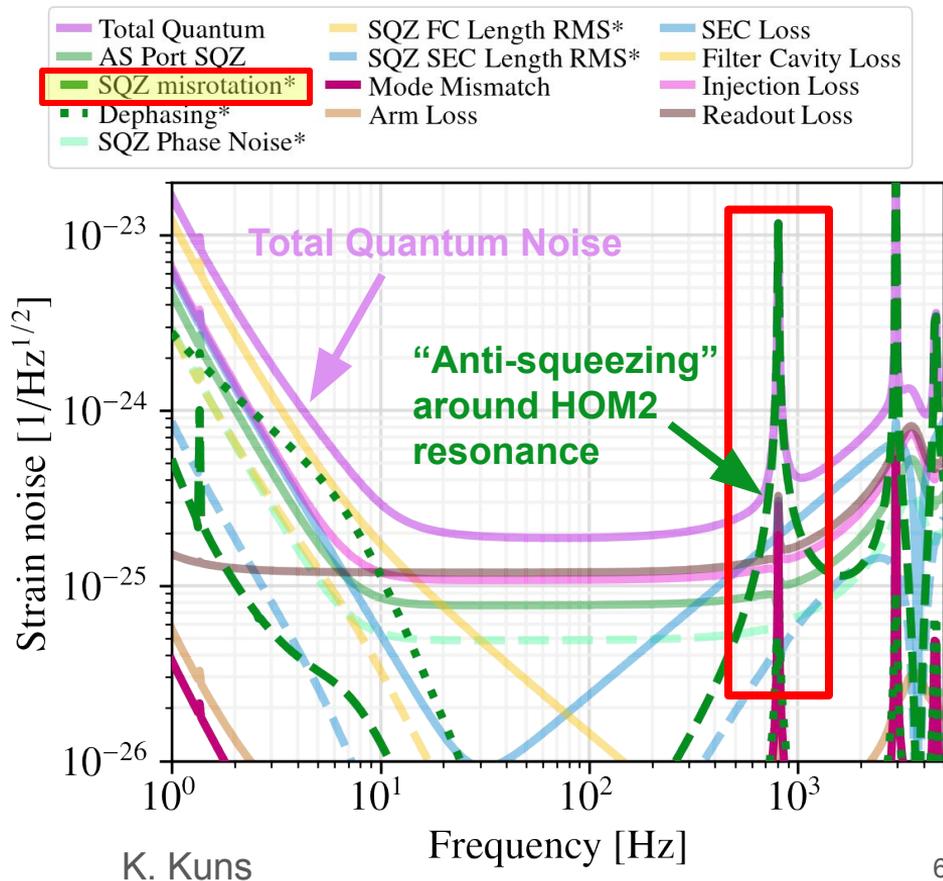

In-band HOM resonances lead to a **coherent mode-scattering** effect:

TEM00 → LG10 → TEM00*

*having accumulated a *different* phase relative to the unscattered TEM00 field (see [McCuller et al. 2021](#))

Results in an **effective rotation of the squeezing angle** relative to the interferometer's readout quadrature (“anti-squeezing”) at frequencies near HOM resonances

Example Quantum Noise Budget with 1% SEC mode-mismatch to arms

Impact of SEC Mode-Mismatch

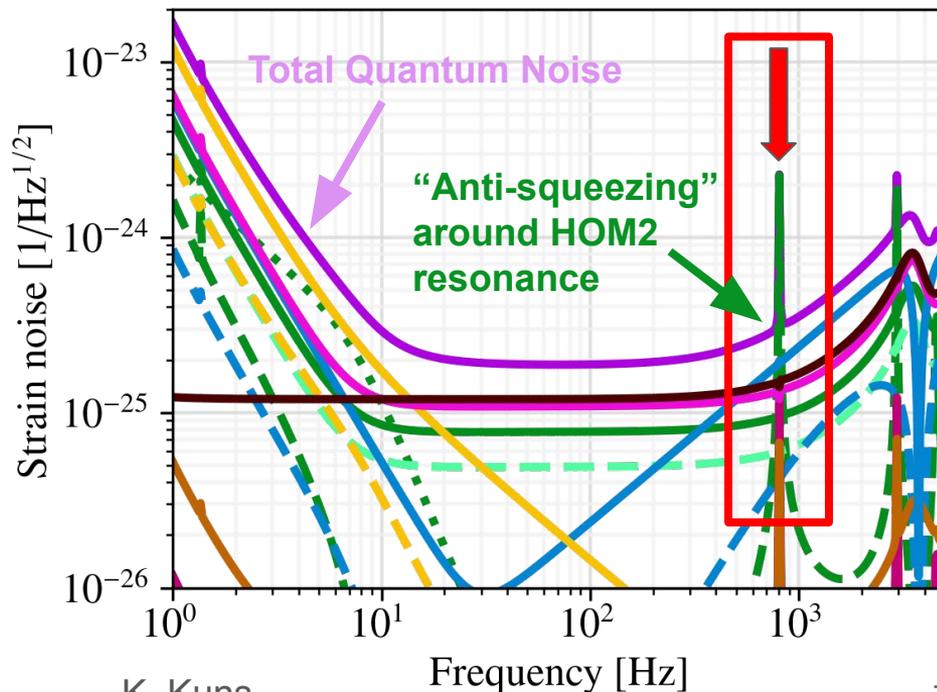

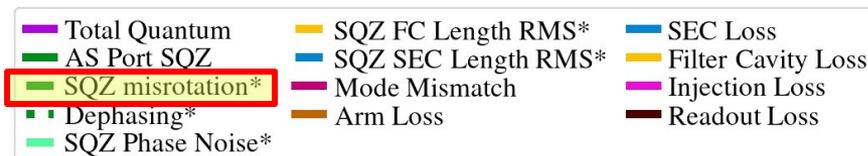

In-band HOM resonances lead to a **coherent mode-scattering** effect:

TEM00 \rightarrow LG10 \rightarrow TEM00*

*having accumulated a *different* phase relative to the unscattered TEM00 field (see [McCuller et al. 2021](#))

Results in an **effective rotation of the squeezing angle** relative to the interferometer's readout quadrature ("anti-squeezing") at frequencies near HOM resonances

Example Quantum Noise Budget with **0.1%** SEC mode-mismatch to arms

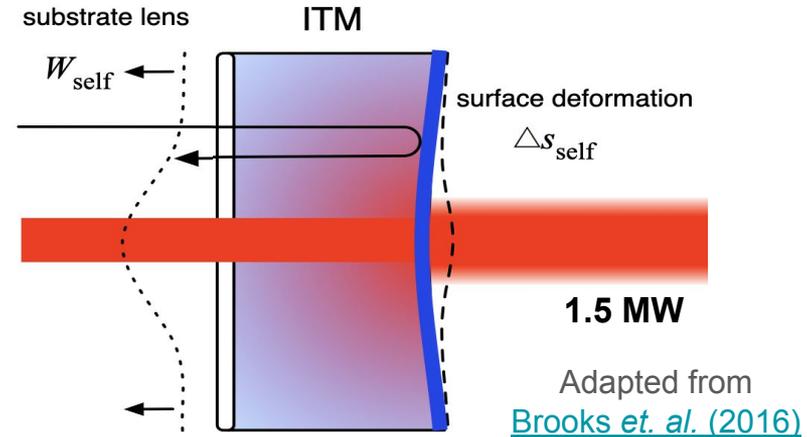

Cosmic Explorer: Why Not Just Scale up LIGO Design?

2) Thermal distortions are a much stronger design driver ([LIGO-G2300624](#))

CE's quantum noise target assumes:

- **1.5 MW** of circulating arm power
4x higher than aLIGO O4
- **10 dB** of frequency-dependent squeezing
 - Requiring **< 500 ppm** SEC loss
10x lower than LIGO A+

Cosmic Explorer: Why Not Just Scale up LIGO Design?

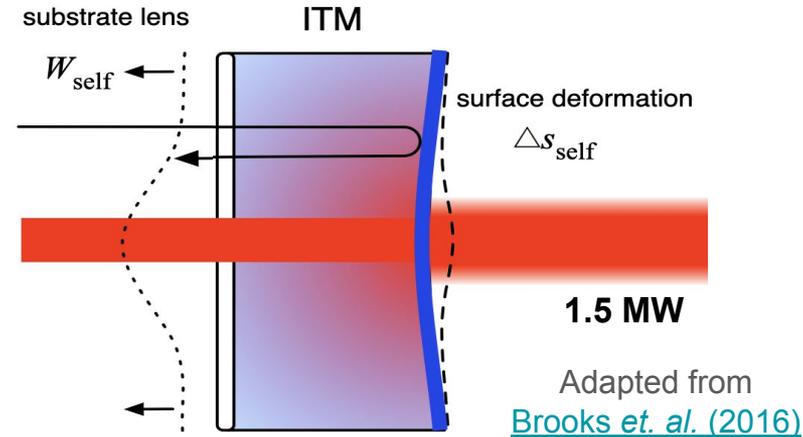

2) Thermal distortions are a much stronger design driver ([LIGO-G2300624](#))

CE's quantum noise target assumes:

- **1.5 MW** of circulating arm power
4x higher than aLIGO O4
- **10 dB** of frequency-dependent squeezing
 - Requiring **< 500 ppm** SEC loss
10x lower than LIGO A+

Overcoming thermal distortions requires:

- Pick-off port locations to **directly sense mode-matching** between cavities
- Cavity **Gouy phases** chosen to minimize impact on squeezing (avoid HOM co-resonances)
- **Higher-precision wavefront control**, beyond radius of curvature correction

Does 500 ppm SEC Loss Preclude 45° Beamsplitter AOI?

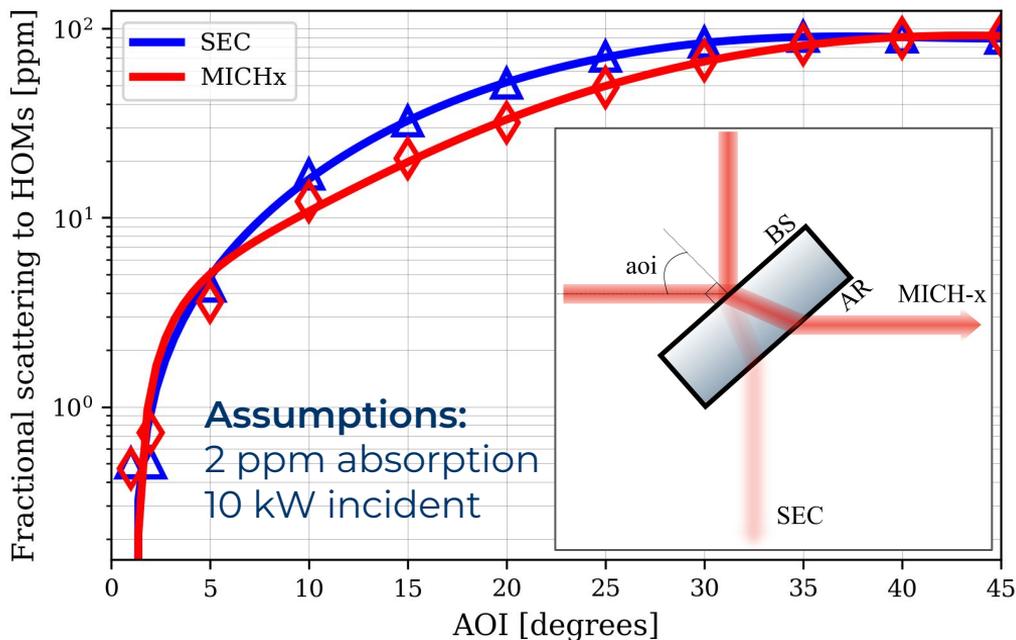

With ~10 kW in the PRC, **thermal lensing in the beamsplitter substrate** is a significant effect

- Uncompensated HOM scattering loss could consume the majority of the SEC loss budget
- **But limited capability to thermally compensate at 45° AOI**

Lower AOI on the beamsplitter:

- Improves the effectiveness of thermal compensation 100x
- Reduces the beamsplitter size requirement by a factor of $\sqrt{2}$

Single-Pass Beamsplitter HOM Scattering *with* optimal thermal compensation

Considered Interferometer Topologies

Two arm specific MSC actuators
 One SEC/PRC specific MSC actuators
 Beam collimated through BS

One arm specific MSC actuator
 Two SEC/PRC specific MSC actuators
 Beam expanding through BS

Additional PRC optics for independent matching to arms

Low AOI on beamsplitter

45deg AOI on beamsplitter

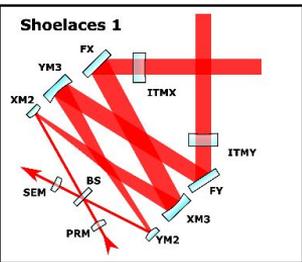

Extra folding mirror required

Needs toroidal M3 mirrors (~22 deg AOI)

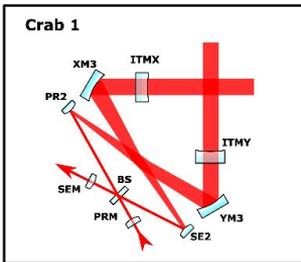

No arm specific MSC actuators

Two arm specific MSC actuators

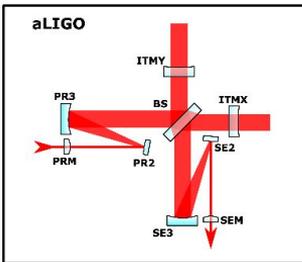

Shoelaces 1

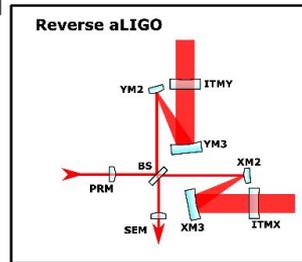

Crab 1

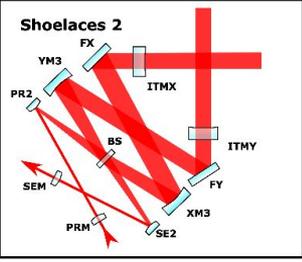

aLIGO

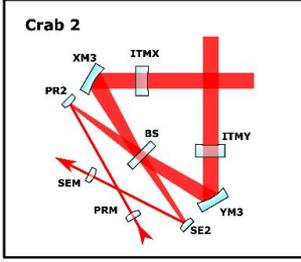

Reverse aLIGO

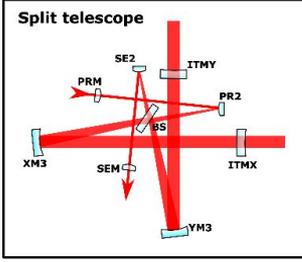

Shoelaces 2

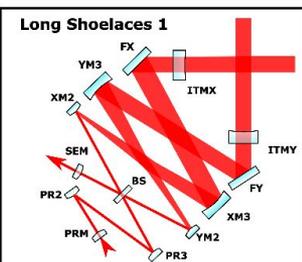

Crab 2

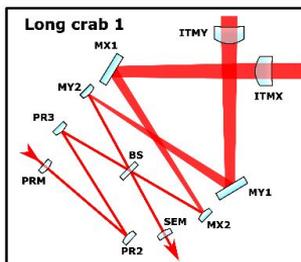

Split telescope

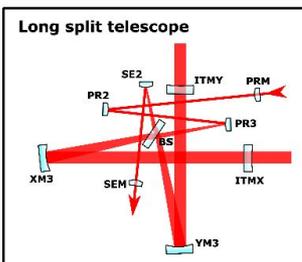

Long Shoelaces 1

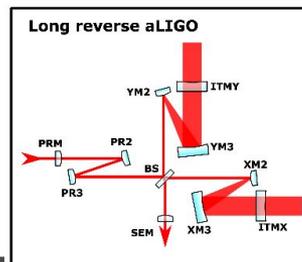

Long crab 1

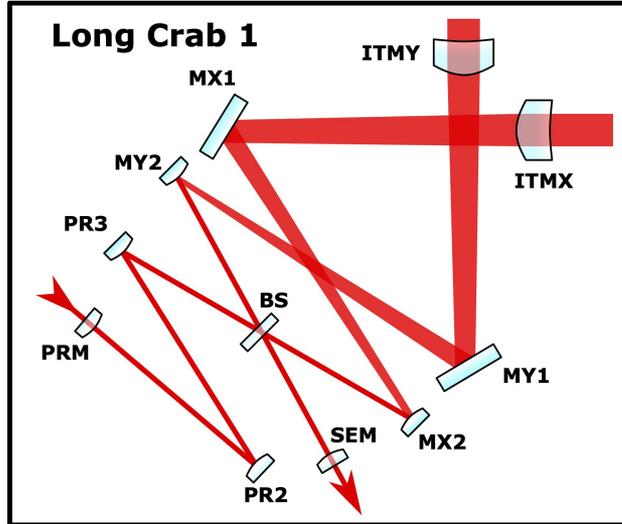

Long split telescope

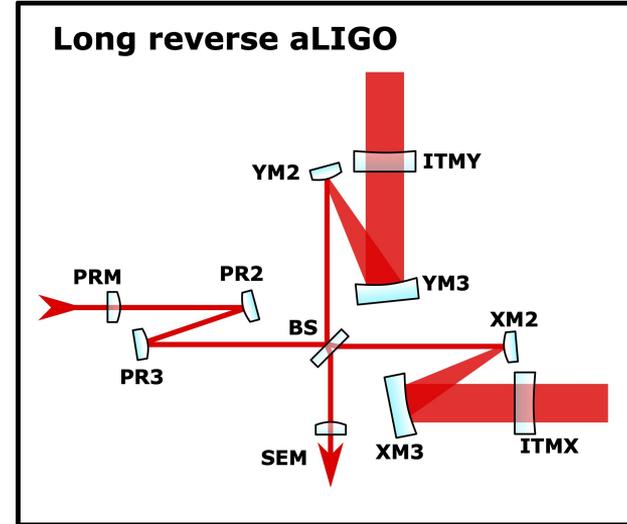

Long reverse aLIGO

Favored CE Interferometer Topologies

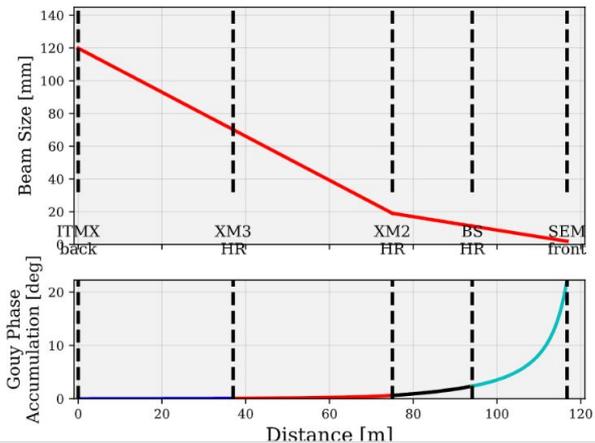

- $\sim 1^\circ$ beamsplitter AOI
- Static lens polished onto ITM AR surface

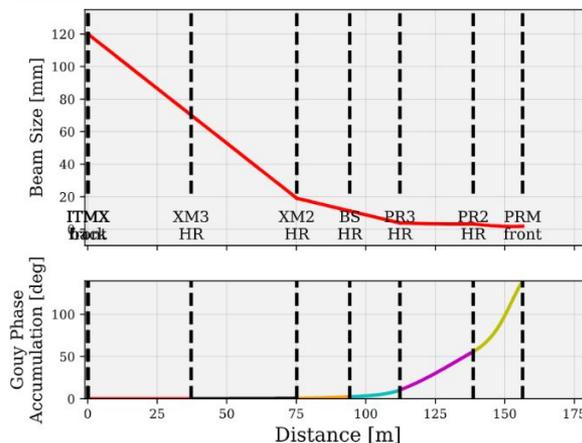

- 45° beamsplitter AOI
- Will benefit from static ITM lens.
- A lower-risk option, *if* beamsplitter thermal lensing is manageable

Concept for Next-Generation Thermal Compensation

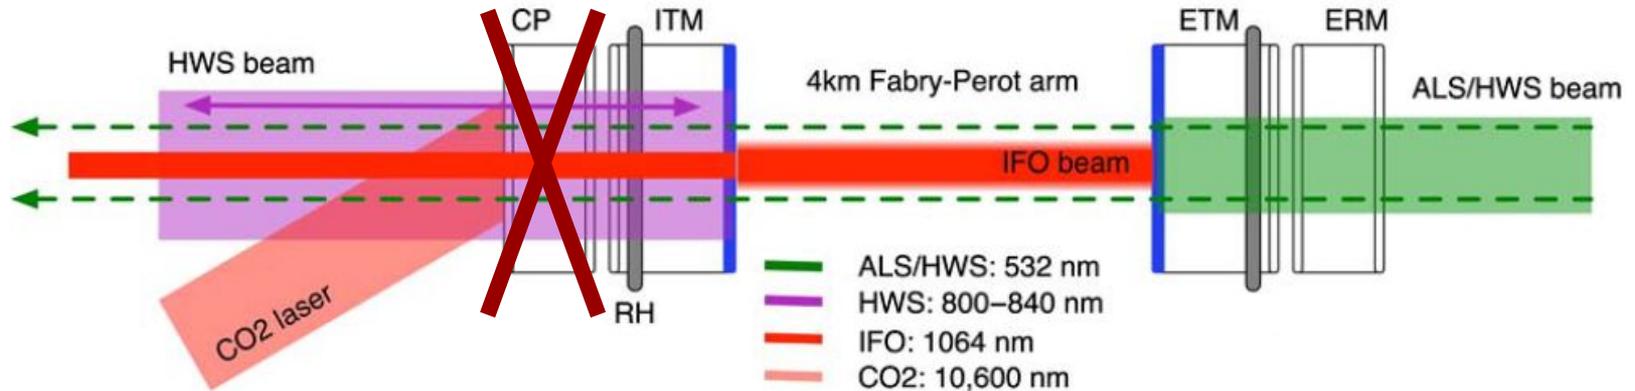

Concept for Next-Generation Thermal Compensation

500 ppm SEC Loss Precludes Compensation Plates

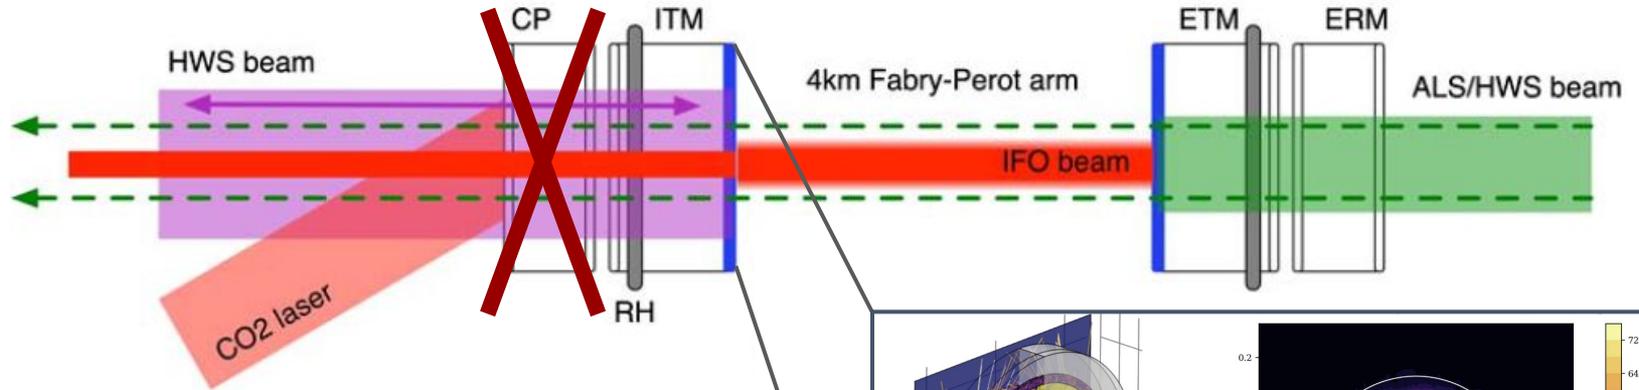

Based on aLIGO AR coatings, expect high-angle scattering loss of **up to 200 ppm** (roundtrip) per compensation plate (CP)

[Brooks et. al. \(2016\)](#)

500 ppm SEC Loss Precludes Compensation Plates

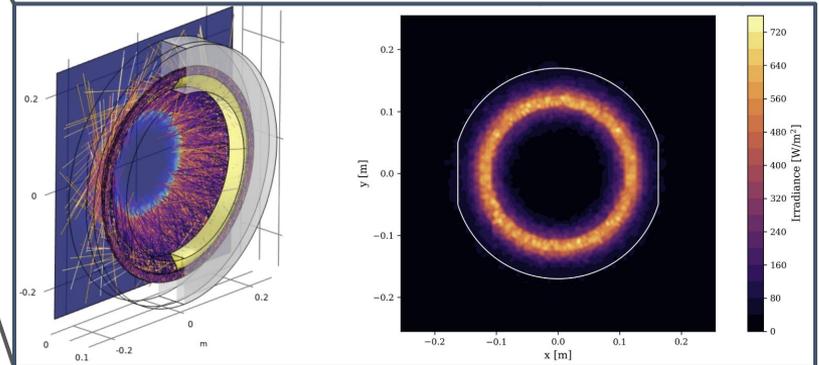

Requires a *qualitatively* new approach to wavefront control, with actuation on **fine spatial scales** (2-5 cm) and **low displacement noise** ($\text{RIN} < 10^{-9}/\sqrt{\text{Hz}}$)

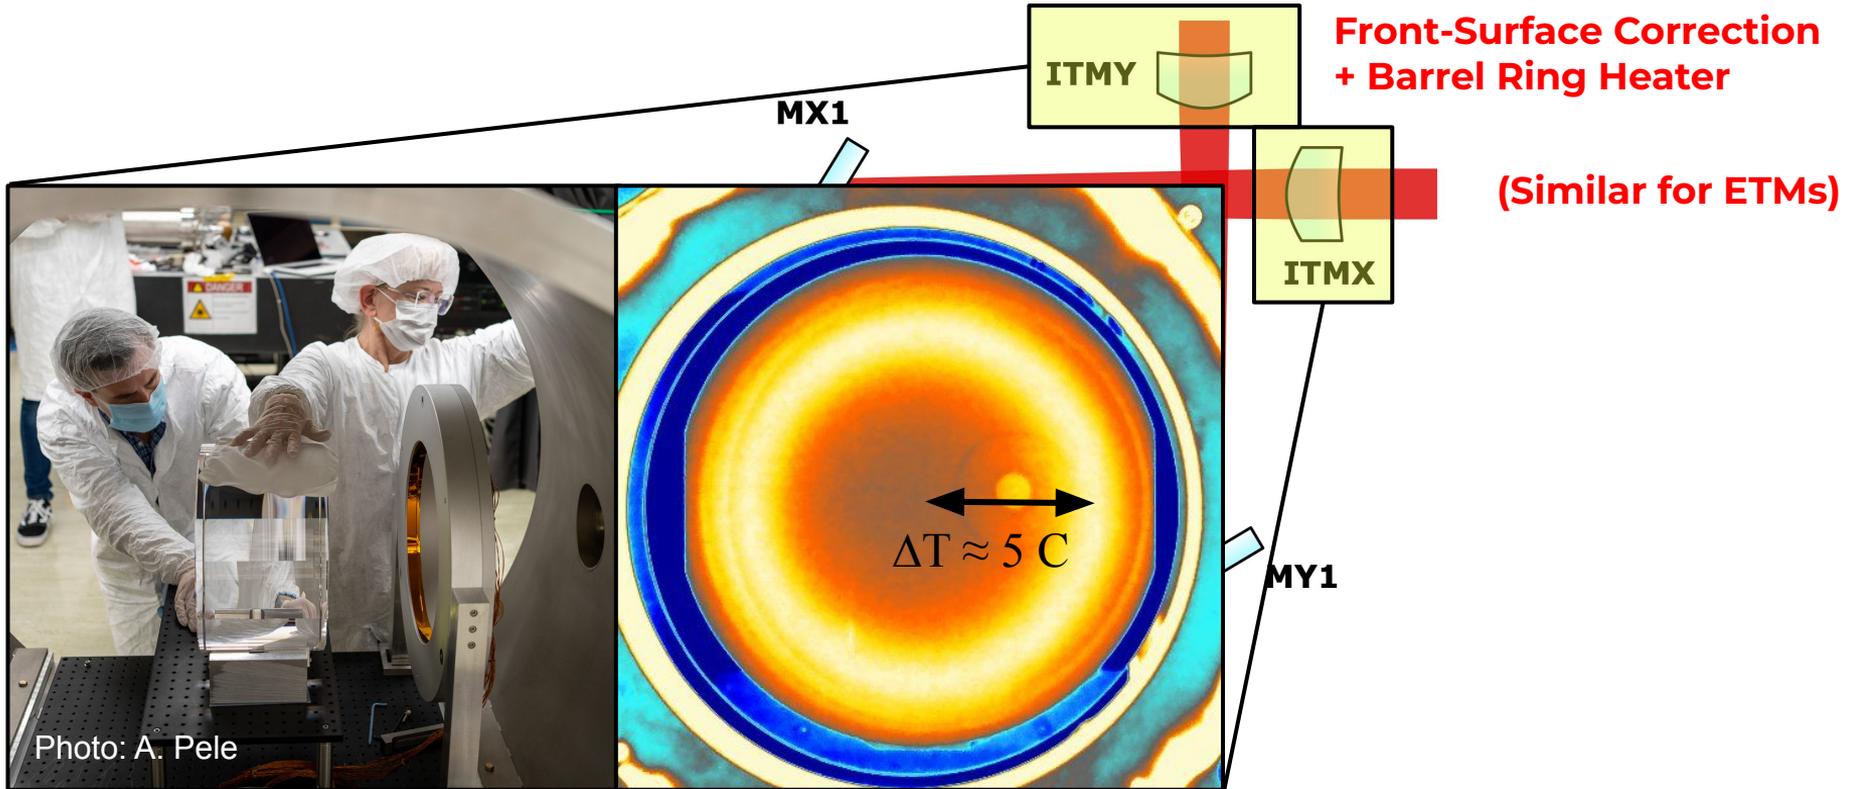

R&D effort underway to develop a CP alternative:

ITM front-surface correction
(used in conjunction with RH)

[CE-G2300032](#), [LIGO-G2400546](#)

Concept for Next-Generation Thermal Compensation

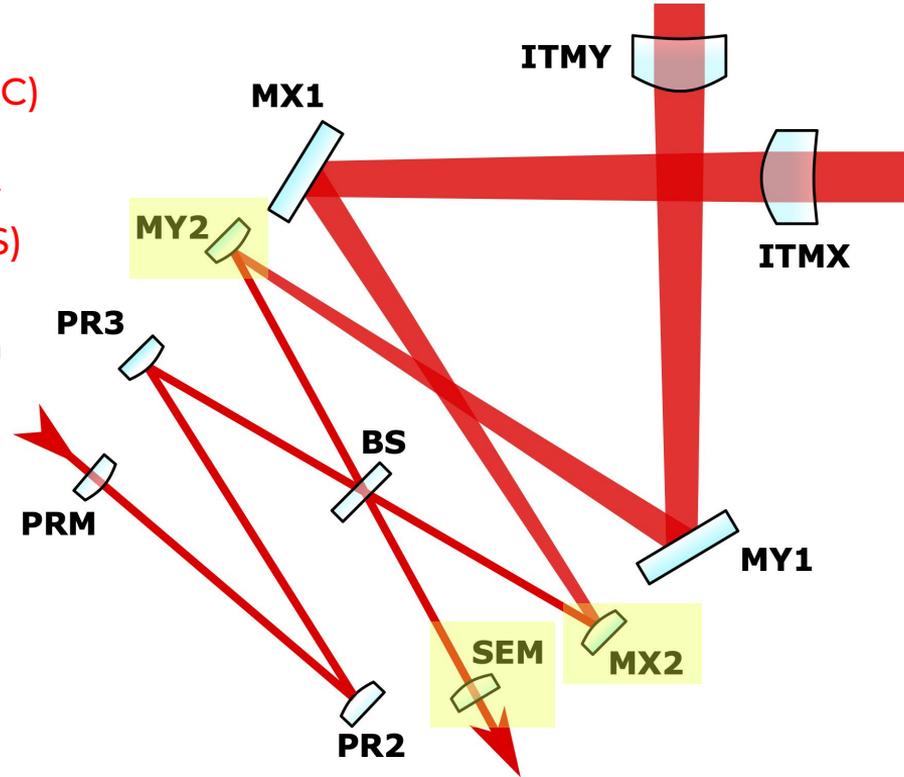

Prototype test at LIGO Lab-Caltech

Measured temperature profile

Concept for Next-Generation Thermal Compensation

SEC Mode-Matching

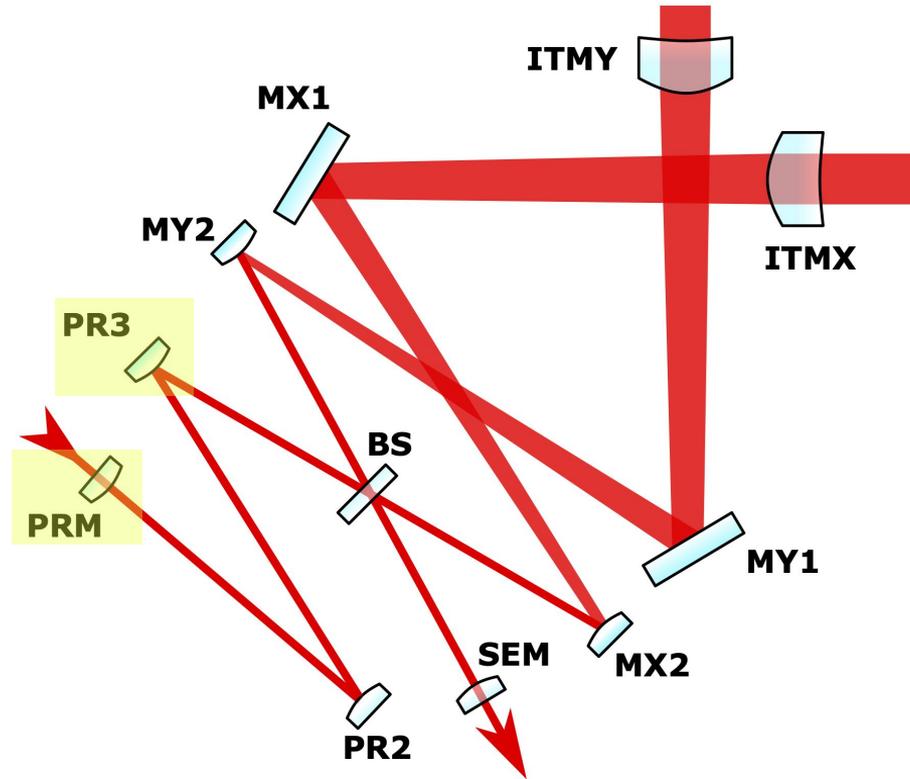

- Three low-order (RoC) actuation points
- Existing technology (ring heater, T-SAMS)
- $> 20^\circ$ Gouy phase separation between MX/Y2 and SEM

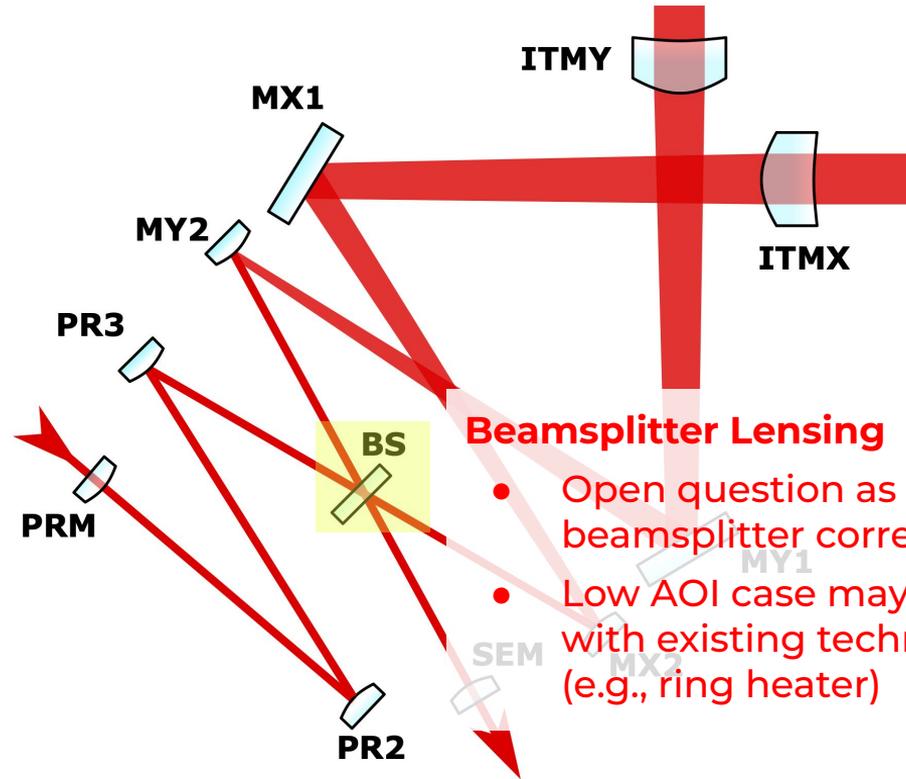

Concept for Next-Generation Thermal Compensation

PRC Mode-Matching

- Two additional low-order (RoC) actuation points
- Less stringent loss requirement allows for additional optics in PRC path
- **Independent control of SEC and PRC mode-matching**
- $> 20^\circ$ Gouy phase separation between PR3 and PRM

Concept for Next-Generation Thermal Compensation

Summary of Technical Challenges

- The many corner layouts studied for CE have been reduced to two contenders, the “Long Reverse aLIGO” and “Long Crab.” **Are there any obvious showstoppers for either of these?**
- One challenge with 40 km arms is that an FSR of 3.75 kHz means every HOM resonance is in-band. **What does this mean for quantum noise performance and laser noise coupling with imperfect mode matching?**
- An additional 40 km arm challenge is sensing CARM, as the arm bandwidth is too low to do what aLIGO currently does. **Are there any alternatives?**
- So far, parametric instabilities have been regarded as a secondary concern, to be addressed later in the design process. **Is this prioritization appropriate?**
- **Which of these risks/topics, or others not listed, are crucial to study now for placing requirements on the infrastructure/facility design?**

Beamsplitter in a strongly converging telescope: concerns

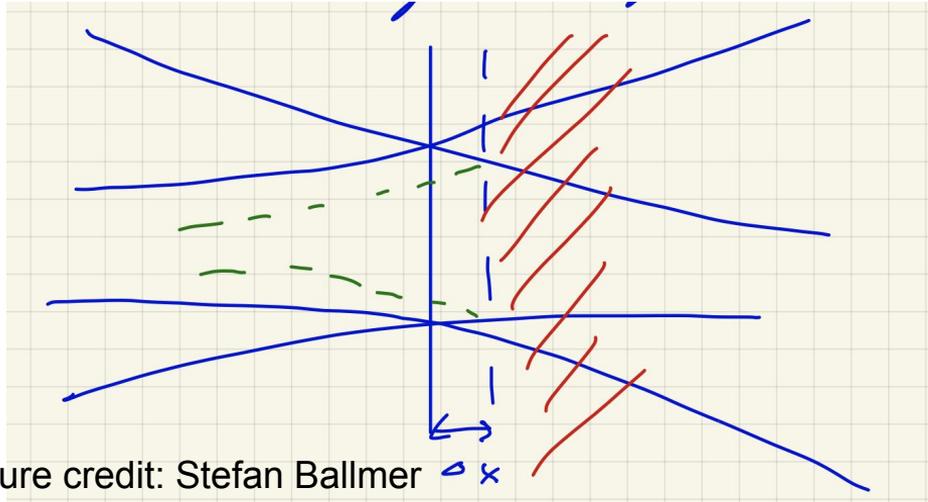

Figure credit: Stefan Ballmer

- Especially at 45deg AOI, coating reflectivity will vary across the beam spot.
- Linear dependence of reflectivity on AOI actually just has a mode matching effect.
- Combines with the more obvious mode matching effect (see sketch).

In words, what matters is directly the Rayleigh length of the beam passing through the BS. For example, if we assume a BS placement tolerance of 5mm, and a maximum acceptable loss of 25ppm, the minimum acceptable Rayleigh length is

$$z_{R,min} = \frac{5\text{mm}}{\sqrt{25 \cdot 10^{-6}}} = 1\text{m} \quad (12)$$

CARM Feedback Main problem

For Cosmic Explorer, the arms will be 40 km long.

The free-spectral range of LIGO is 38 kHz.

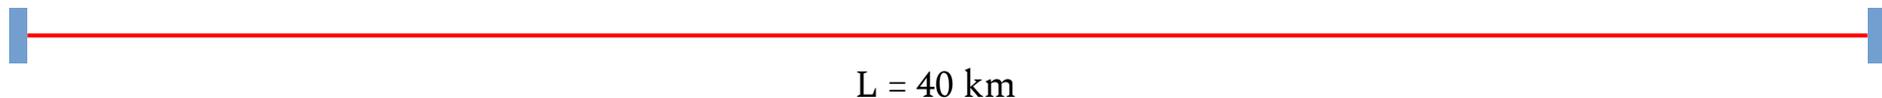

The free-spectral range of Cosmic Explorer is 3.8 kHz.

	Advanced LIGO	Cosmic Explorer
Arm Length	4 km	40 km
FSR	38 kHz	3.8 kHz
CARM pole	0.4 Hz	0.04 Hz

vs

Cosmic Explorer

Problem: LIGO's current frequency stabilization bandwidth is around 30 kHz.

However, the controller cannot extend beyond the FSR due to the overcoupled arm cavity phase dynamics.

Additionally, the extremely low linewidth (0.04 Hz) makes the CE shot noise limit insufficient at 500 Hz.

Solution: do not rely on CARM for HF feedback

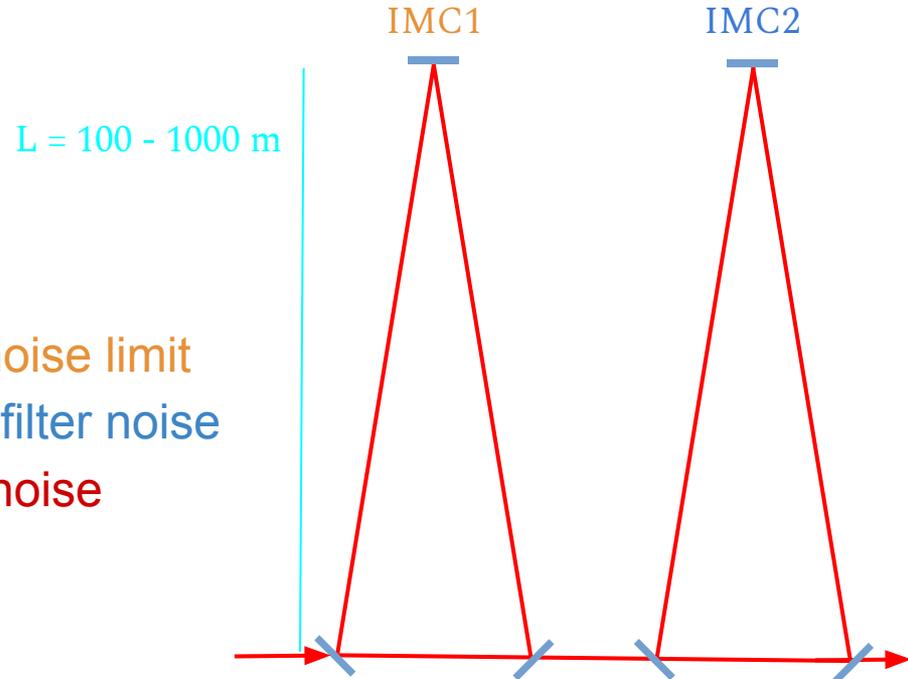

Do not rely on the interferometer
for frequency noise suppression

Instead, use two long input mode cleaners

First IMC is high-bandwidth to reach shot noise limit
Second IMC is low-bandwidth to passively filter noise
Main interferometer will also strongly filter noise

Advantages:

- 1) Long cavity is a better frequency reference
- 2) No feedback from IFO required

Simulation tools for CE optical design

- Finesse 3
 - For noise couplings, quantum noise calc., closed loop controls.
- pyGWINC
 - Noise budgets, science metrics.
- SIS
 - High-order scattering, stray light modeling.
- GTrace, Zemax, ...
 - Geometrical layouts, ghost beams.
- FEA tools
 - COMSOL, ANSYS
 - FEniCSx (open-source)
- Time domain optical modeling software.
 - Lock acquisition, glitch response, ...
- ...others we should be aware of?
- ...physics that is needed but not covered by these?

Optical design team organization

- CE mailing list: optdes@cosmixexplorer.org
- Weekly Zoom calls, Monday 4pm EST. Alternating:
 - Week A “formal” call, with progress updates.
 - Agenda, notes and recordings stored on [CE DCC here](#) under different document versions.
 - Week B “informal” workshop-style call.
 - Students encouraged to bring modeling questions etc.
- Mattermost Channel used for discussion among project members.
- Mattermost Board used for coordination of tasks.
- Gitlab instance used for optical design modeling repositories.

The screenshot shows a project management interface for 'CE optical design'. It features a progress tracker at the top with three columns: 'Not Started' (10 items), 'In Progress' (4 items), and 'Completed' (4 items). Below the tracker are several task cards, each with a title, a priority indicator (e.g., '1. HIGH'), and a status icon. The tasks include: 'Calculate beamsplitter reflectivity variation over beam size for curved wavefront.', 'Corner layout-agnostic recycling cavity design', 'Calculate beam splitter mechanical modes vs size for fixed aspect ratio', 'Investigate mode hopping', 'Investigate Gouy phase effects on SQZ degradations and carrier/sideband PRGs and error signals', 'Make Corner Layout git repo', 'Make IMC design git repo', 'Make initial "default" mode-matched Finesse Crab 1 model', 'Make RH and FROSTI profiles for CE test masses', 'Make initial "default" mode-matched Finesse Crab 2 model', 'Make initial "default" mode-matched Finesse Split Telescope model', and 'Write up technical note on corner layout down select'. A '+ New' button is visible at the bottom right of the task grid.

The screenshot shows a GitLab repository page for 'Cosmic Explorer Corner Layout'. The page includes a breadcrumb trail 'main / cosmic-explorer-corner-layout / +', navigation buttons for 'History', 'Find file', 'Edit', and 'Code', and a recent commit by Kevin Kuns. Below this is a table of repository contents:

Optical design NSF award

Design work split into 4 work packages:

Core optical design

Interferometer sensing and control.

Laser stabilization and lock acquisition.

Readout and quantum enhancement.

Key project deliverables:

Conceptual design of CE interferometers, performance consistent with science targets.

Subsystem requirements specifications.

Interferometer noise budget (beyond fundamental noises).

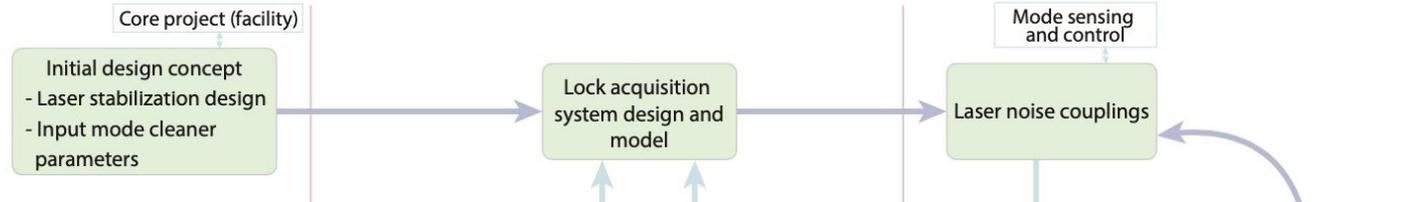

Reference simulation models for CE IFOs.

We are here

CE optical design basics

Interferometers are *frequency-dependent squeezing-enhanced dual-recycled Fabry-Perot Michelson interferometers* (like A+).

40km and 20km arm lengths.

Longer arms (at same finesse) means lower FSR (and cavity pole).

SEC finesse must be higher to retain broadband response.

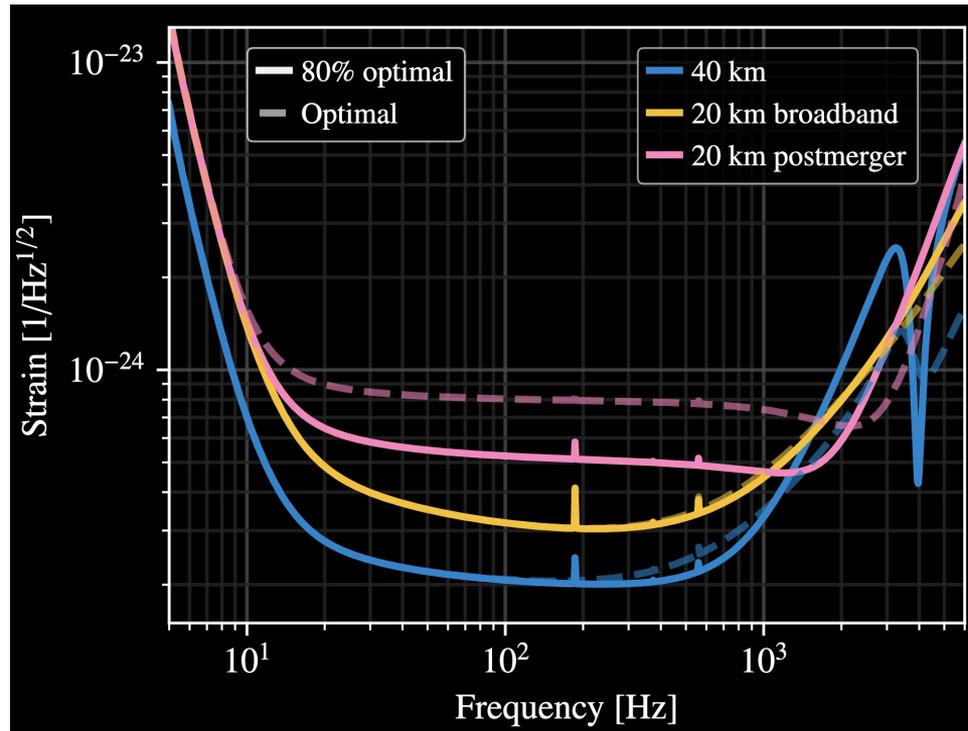

Beam radius on TMs ~12cm.

1.5 MW circulating arm power.

Stable recycling cavities.

Balanced homodyne readout.

SEC length effect on sensitivity to post-merger signals

In CE the SEC resonance falls within the detection band (unlike aLIGO), especially for long SEC.

This can reduce sensitivity around 2kHz, where BNS post-merger signal lives. 80% reduction from optimal post-merger sensitivity when:

L_{SEC} 20m \rightarrow 200m (CE 40km)
 L_{SEC} 25m \rightarrow 90m (CE 20km post-merger tuned).

For reference, aLIGO $L_{\text{SRC}} \sim 55\text{m}$.

Optical design challenge is to keep SEC short within other constraints (e.g. beam size reduction from arms to output).

SEC length effect on sensitivity to post-merger signals

Question to consider:

Maintaining the post-merger sensitivity places what seems to be a challenging constraint on SEC length for the 20km IFO.

Might we need to review a science case trade on this item?

Laser wavelength: accommodating 2 μ m

CE baseline design is for 1064 nm.

Potential upgrades include a Voyager-like configuration in the future.

Cryogenic silicon test masses.

Laser wavelength required to change to $\sim 2 \mu\text{m}$.

Challenge is to avoid **facility** constraints that will make this “difficult”.

Examples:

Baseline beam size for 2 μm over 40 km is 16.5 cm

Would want higher arm finesse ($\sim 3\times$) to take advantage of better thermal handling (which would also remove benefit of 20 km post-merger tuning) Section 8.4 of the horizon study.

Question: *To what degree do we need to keep these things in mind as we proceed with the 1064nm design?*

Frequency noise mitigation

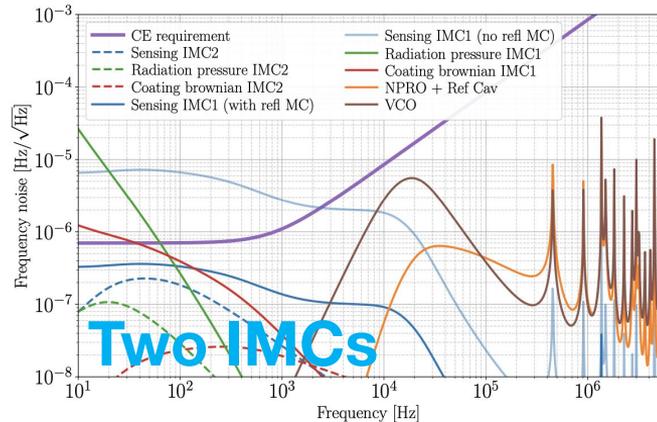

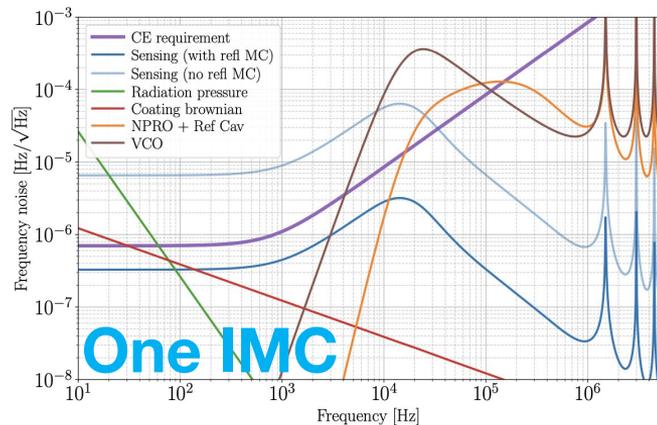

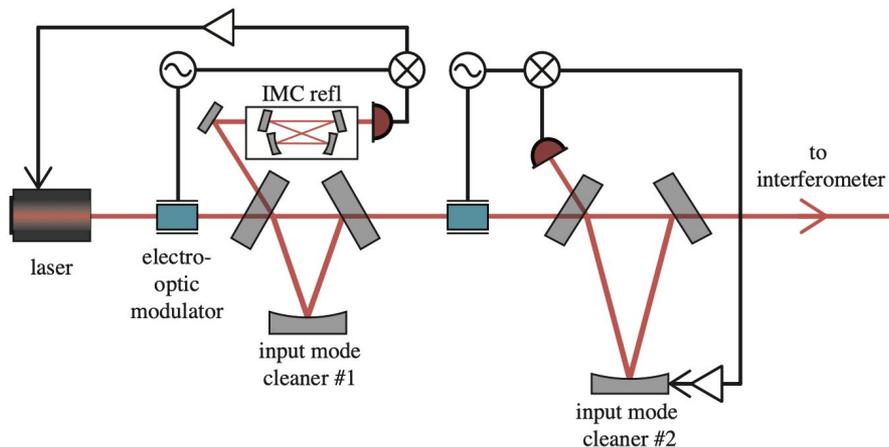

Low arm FSR precludes using arms as in-band frequency reference (UGF too low).

Alternative scheme uses a long (100m+) input mode cleaner as frequency reference.

Second mode cleaner may be needed for passive filtering (also IMC refl. Mode cleaner).

Mode Sensing and Control Project Summary

Actuators Work Package

We are here

Summary of MSC Challenges

- **MSC will drive optical topology of entire interferometer**
 - E.g., Beamsplitter AOI
- **CE's quantum noise target (1.5 MW / 10 dB SQZ) requires:**
 - <1% mode-mismatch between interferometer cavities
 - <500 ppm loss in Signal Extraction Cavity (SEC)
- **Requires a new generation of wavefront actuators**
 - Apply more accurate wavefront correction to test masses under extreme thermal loading
 - Eliminate the transmissive compensation plates relied on by LIGO
- **Requires closed-loop sensing and control of these actuators**
